Foreword

Rice varieties are bred for higher yield and imparting other unique traits for tolerance/resistance to biotic and abiotic stresses and superior grain quality. The grain yield of rice varieties varies in different regions of India. Eastern India shows relatively less yield due to predominant rain-fed cultivation. National Rice Research Institute (ICAR-NRRI), Cuttack, Odisha has released 139 rice varieties including three hybrids. The previous analysis of area covered by NRRI varieties provided insights on the role of NRRI varieties on national food security. The present analysis on the different traits of NRRI varieties namely yield trend, yield index, grain quality including glycemic index, resistant starch, straw quality and response to biotic and abiotic stresses further complements the previous analysis and provides additional insights in the phenotypic diversity of NRRI varieties. For example, NRRI varieties are more popular in the rainfed, shallow lowland and irrigated ecologies. Also, the rate of increase in the yield for NRRI varieties ($0.022\text{ t ha}^{-1}\text{year}^{-1}$) is similar to the national average. Ecologies such as irrigated, shallow lowlands, deep water showed increasing trend in yield over years. Further, varieties namely Shaktiman, Savitri showed very less glycemic index. The biotic stress response of NRRI varieties indicates presence of resistance for major diseases and pests of rice. Straw quality analysis of NRRI varieties provides valuable information for the utilization of paddy straw for various purposes. Thus, the present bulletin is not only an account on the unique traits of NRRI varieties but also provides insights in the long-term objectives of researchers through which varieties are developed by the institute. Additionally, future needs of rice farmers especially in eastern India are going to be entirely different as compared to the previous few decades. In this regard, integration of the data obtained in the present analysis will greatly assist in fine-tuning the objectives of development of rice varieties to suit the farmers' need.

I sincerely appreciate the scientists of NRRI, Cuttack for bringing out this timely, valuable document on the different traits of NRRI varieties and strongly believe the information available in this research bulletin will inspire and encourage rice scientists for developing highly profitable, climate-smart, consumer demand driven rice varieties catering to the future need of rice farmers in our country.

(H. Pathak)

PREFACE

Preface

ICAR - National Rice Research Institute (ICAR-NRRI), Cuttack, Odisha has released 139 rice varieties including three hybrids. Our previous analysis of total rice area covered by NRRI varieties showed popularity of NRRI varieties especially in Odisha and West Bengal. Further, scientists from different divisions individually analyzed the NRRI varieties for general traits such as yield, ecologies, duration, grain related traits including glycemic index, straw quality, biotic and abiotic stress responses. Therefore, compilation of all the analyzed traits of NRRI varieties was initially conceived for better understanding of the phenotypic diversity of NRRI varieties. In this regard, seven general traits of NRRI varieties, eleven grain related traits including glycemic index and resistant starch, nine biotic stresses, four abiotic stresses, yield trend analysis over years, duration, ecologies, grain type and straw quality were analyzed in this research bulletin. For the analysis, varietal traits data of NRRI varieties were collected from the individual scientists and analyzed for mean values, grouping into different phenotypic classes and tabulation was done for each traits studied. Further, data points for different traits were also verified individually and pictorial representation for all the traits analyzed was made. Further, based on the bar charts for the different traits, preliminary draft was prepared and extreme values of traits were removed from the analysis in preparing final draft. We request the readers to initially go through the charts for different traits in order to understand the general trend of NRRI varieties and annexures can be referred for specific information. We hope that most of the data on the phenotypic diversity of the NRRI varieties provided by the scientists are included in this research bulletin.

We gratefully acknowledge all the scientists of NRRI for providing the data about NRRI varieties, without them the compilation of this research bulletin could not be possible. We sincerely believe this research bulletin provides insights to the rice scientists and could be very useful in designing the breeding program for development of rice varieties in future.

Authors

SUMMARY

Summary

ICAR-NRRI, Cuttack has released 139 varieties so far including three hybrids. NRRI varieties are popular among the farmers in eastern India especially in the states of West Bengal and Odisha. Our previous analysis showed that NRRI varieties cover an area of about 7.91Mha in India. However, varietal traits, grain and straw quality and reaction of NRRI varieties to biotic/abiotic stresses are not reported so far. Thus, the present research bulletin highlights seven general traits of NRRI varieties, eleven grain related traits including glycemic index and resistant starch, straw quality, nine biotic stresses, four abiotic stresses and yield trend analysis for duration, ecologies and grain types over the years. The analysis showed ~54.47% of NRRI varieties were released for two ecologies namely irrigated and shallow lowlands. The medium duration varieties (121-135 days) provided higher yield ($>5\text{ t ha}^{-1}$) as compared to long duration NRRI varieties. However, rate of increase in the yield of NRRI varieties is $0.022\text{ t ha}^{-1}\text{year}^{-1}$ over years which are found to be similar to national average. The predominant grain type of NRRI varieties is medium and long slender. The varieties namely Sonamani, Swarna-Sub1, Lunabarial showed greater head rice recovery, HUE and Geetanjali showed higher grain length and kernal length after cooking (KLAC), Shaktiman, Savitri showed low glycemic index (<60). Further, response of NRRI varieties to biotic and abiotic stresses is also highlighted in this bulletin. The varieties namely Savitri, Panidhan, and Sumit showed resistance to blast due to presence of nine blast resistance genes. Additionally, varieties namely Sarasa, Neela, Nua Kalajeera, Swarna Sub1, Poorna Bhog showed resistance to bakanae, and varieties Sarala, Hazaridhan, Satyakrishna, Reeta were moderately resistant for brown spot diseases. Similarly, Reeta and Lunasampad showed moderate resistance to rice root knot nematode and brown plant hopper, respectively. Variety Samalei showed resistance to gall midge. In particular, popular varieties for shallow lowland ecologies namely Pooja, Sarla, Gayatri were also found to be tolerant to stagnant flooding (30cm water depth). Further, paddy straw quality analysis has identified few varieties most suited for composting because of higher nitrogen content on dry matter basis. Thus, the present bulletin provides comprehensive information related to the characteristics of NRRI varieties along with grain traits, which will be useful for the rice researchers in designing the breeding program for rice improvement.

1. Introduction

ICAR-National Rice Research Institute (ICAR-NRRI), formerly known as Central Rice Research Institute (CRRI), initiated the hybridization program for development of high yielding rice varieties from 1960 onwards. The institute has released the first variety fifty years back named as 'Padma'. The institute has so far released 139 rice varieties of different ecologies including three hybrids for cultivation. The high yielding, nitrogen responsive rice varieties made India self-sufficient and varieties released after green revolution resulted in five-fold increase in rice production. However, addressing the challenges of rice farming due to climate change, low profitability, below optimum productivity requires special efforts to sustain the food security in coming decades. Therefore, it is of prime importance to understand the traits, salient features, and farmer's preference of released NRRI varieties in order to structure the breeding program to meet the upcoming challenges.

2. Methodology

2.1. Traits analysis of NRRI varieties

The traits namely average yield, grain type, ecologies, duration were collected for NRRI released varieties, analyzed for mean and grouped into distinct classes for further analysis. Linear regression model was used for yield trend analysis over the years considering year of release of variety as a function of yield of NRRI varieties by using the linear equation $y = ax + b$, where y is yield of the NRRI variety, x is year of release and b is the constant. Similar trend analysis was also performed for different traits such as duration, ecologies, and grain type. Breeder seed indent for NRRI varieties were taken from the annual report of AICRIP-National seed project (crops), Indian Institute of Seed Science, Mau (2017-18). The area covered by NRRI varieties was taken from Pathak et al. (2018).

2.2. Biotic stress screening

Rice leaf blast screening was conducted at Uniform Blast Nursery (UBN), NRRI, Cuttack. Each variety (30 plants per test entry) was planted in 50 cm long rows in nursery beds at spacing of 10 x 10 cm. The susceptible checks (HR12 and CO39) were sown in borderlines as spreader rows and as well as after every five test entries for uniform spread of the disease. Disease reaction was recorded twenty five days after sowing and continued up to 40th day after sowing or spreader row per checks achieved 85% of the disease symptom (Susan et al, 2018). Sheath blight disease screening was performed by artificial inoculation under field condition by inserting the sclerotia of virulent *Rhizoctonia solani* isolate. Artificial seed inoculation method was used for screening against bakanae disease as described by Fiyaz et al. (2014). The virulent isolate of *Sclerotium oryzae* was mass multiplied in the sand-maize medium, mixed with the sterilized pot soil @ 15 g kg⁻¹ of soil and utilized for screening against seedling blight disease of rice. Varietal screening of Brown plant hopper (BPH) was carried out as per

the procedure followed by Anonymous et al. (1975) and Jena et al. (2015). NRRI varieties were evaluated against rice root knot nematode by releasing a J2 per g of soil. The test entries were screened against gall midge biotype GMB2 in greenhouse as per the standard protocols (Vijaya et al. 2006).

2.3. Resistant starch and glycemic index analysis

Resistant starch and glycemic index of NRRI varieties was analyzed as reported by Kumar et al. (2018).

2.4. Straw quality parameters

NRRI varieties have been evaluated for different paddy straw qualities as reported by Subudhi et al. (2020).

3. NRRI varieties: Salient features

3.1. No. of NRRI varieties

The institute has released so far 139 rice varieties including three varieties were identified for release during 2019 (Fig. 1, Annexure I). In the last nine years, 51 varieties were released and are preferred by the farmers for cultivation. Recently, varieties for high protein rice, high zinc rice, and multiple biotic and abiotic stress tolerant varieties have been released for cultivation through backcross breeding (Table 1). Also, multiple MOUs have been signed with the private companies for marketing of NRRI varieties, in particular for three hybrids developed in the institute. Thus, varieties released from NRRI are being cultivated by the farmers of eastern India in general, and particularly in Odisha and West Bengal.

Fig. 1. NRRI varieties released in the last 50 years.

Table 1. Varieties of NRRI developed using marker assisted selection.

Variety	Year of release	Ecology	Genes/QTLs introgressed
1. Swarna-Sub1	2009	Flood prone, shallow lowland	<i>Sub1</i>
2. Improved Lalat	2012	Irrigated	<i>xa5, xa13, Xa21</i>
3. Improved Tapaswini	2012	Irrigated	<i>xa5, xa13, Xa21</i>
4. CR Dhan 800	2016	Shallow lowland	<i>Sub1, xa5, xa13, Xa21</i>
5. CR Dhan 801	2018	Shallow lowland	<i>Sub1, qDTY1.1, qDTY2.1, qDTY3.1</i>
6. CR Dhan 802	2018	Shallow lowland	<i>Sub1, qDTY1.1, qDTY2.1</i>

3.2. Area covered by NRRI varieties in India

NRRI varieties are widely grown in different states of India (Fig. 2) (Pathak et al. 2018). The major states growing NRRI varieties are West Bengal, Odisha, Chhattisgarh, Uttar Pradesh, Bihar, Jharkhand, and Tamil Nadu including few other states. The total area covered by NRRI varieties is 7.91 Mha in India. The two states namely West Bengal and Odisha cover nearly 50% area of NRRI varieties in India.

Fig. 2. Area of NRRI varieties grown in different states of India.

3.3. Popular NRRI varieties in formal seed chain

The breeder seed indent of NRRI varieties shows ~54 varieties are in breeder seed chain. During 2017-18, major varieties namely Sahbhagidhan, Swarna-Sub1, Pooja, CR Dhan 201, Abhishek, Sarala, Naveen were indented through breeder seed indent (Fig. 3). These varieties were grown in ecologies such as rainfed upland, flood prone shallow lowland, shallow lowland, aerobic, medium deep, irrigated, boro, deep water and irrigated conditions. Moreover, variety Maudamani is spreading through informal seed chain especially by farmers to farmers transfer in Odisha.

Fig. 3. Demand of breeder seed of popular NRRI varieties.

3.4. Ecology-wise NRRI varieties

The NRRI varieties are very popular among the farmers of different states in India. Among the 139 rice varieties released by NRRI, Cuttack, 20 varieties were released for upland, 49 varieties were released for irrigated ecology, 28 varieties for shallow lowlands, 21 varieties for deep, semi-deep and medium deep ecologies, 6 varieties for coastal salinity ecology, 10 varieties for aerobic ecology and few varieties have been released for bunded-uplands, rainfed, and boro ecologies in India (Fig. 4). Varieties such as Sahbhagidhan, Pooja, Naveen, Shatabdi, and Savitri are very popular among the farmers in India. Also, it is estimated that NRRI varieties are grown in an area of 7.9 Mha and generates a gross annual returns of Rs. 48,643 crores in India.

Fig. 4. Ecology-wise suitability of NRRI varieties.

3.5. Yield trend of NRRI varieties

The average yield of NRRI varieties recorded in AICRIP trials were analyzed for understanding the long-term trend in the yield of NRRI varieties. The linear regression curve for yield over years has showed that mean yield of the varieties has increased from 3.5 t ha^{-1} in 1968 to 4.6 t ha^{-1} in 2018 (Fig. 5a). Even though, yield of NRRI varieties has improved by over 1 t ha^{-1} , but the rate of increase of mean yield of NRRI rice varieties was only $0.022 \text{ t ha}^{-1} \text{ year}^{-1}$. The release of varieties in different ecologies especially rainfed upland and lowlands could be one of the major reasons for very less yield increase per year during the last 50 years. Further, ecosystem-wise yield trend analysis showed that varieties released for deep and medium-deep ecologies have the highest yield increase over the years as compared to other ecologies. Additionally, varieties of shallow lowlands, irrigated and upland ecologies showed similar trend of yield increase and remaining ecologies showed more or less stable yield increase over years (Fig. 5b). Similarly, yield trend was also analyzed for the duration of varieties over years in different ecologies. In the analysis, long duration varieties of deep and semi-deep water showed increase in the yield. Similarly, irrigated, aerobic, upland varieties also showed increased yield trends for increase in the duration of the varieties. However, coastal salinity, shallow lowlands and medium-deep varieties showed reduced yield trends for increase in the duration of the varieties (Fig. 5c). Additionally, grain type of NRRI varieties were also analyzed for yield trend over the years. In the analysis, except for long bold varieties, long slender, medium slender, and short bold showed increasing yield trend over years (Fig. 5d). Thus, yield trend analysis indicates different breeding efforts are required to increase the average yield of varieties for various ecologies.

Fig. 5a. Yield trend of NRRI varieties.

Fig. 5b. Ecology-wise yield trend of NRRI varieties.

3.6. Relationship between yield and duration

Yield is a function of multiple traits. Crop duration is one of the important traits which determine the yield of the varieties. The analysis in NRRI varieties showed increase in duration from 60 to 135 days also increased the mean yield of the varieties (Fig.6a). However, mean yield reduced for varieties with duration of 136-170 days. The decrease in the yield of long duration varieties might be due to release in adverse ecologies namely shallow lowland, coastal saline, deep water ecologies. The highest mean yield of 4.78 t ha^{-1} was achieved for varieties of irrigated ecology (121-135 days). Further, linear regression for yield and duration of NRRI varieties was found to be, $Y = 0.011x + 2.824$, where Y is the yield of the variety, x is the duration of the variety and 2.824 is the regression constant (Fig.6b). The linear equation was used to calculate the difference between the expected yield and observed yield for a duration of a variety. The varieties showing highest yield index was selected for each ecologies and given in Table 2. The highest index value indicates varieties showing greater yield for the respective duration.

Fig. 6a. Duration and yield of NRRI varieties.

Fig. 6b. Duration and yield relationship of NRRI varieties.

Table 2. Ecology-wise yield index of NRRI varieties.

Sl. No.	Variety	Ecology	Yield ($t ha^{-1}$)	Duration	Expected Yield	Yield index

* All the varieties in deep water has the duration between 160-162, thus any NRRI variety can be recommended

3.7. Grain type, hulling, milling and head rice recovery of NRRI varieties

Rice grain morphology is an important criterion for the preference of variety by the consumers. The specific requirements of the consumers change from place to place. The majority of the NRRI varieties are medium slender, followed by short bold and long slender (Fig. 7, Annexure II). The least number of varieties has medium bold gain type. Moreover, more than 50% of NRRI varieties comprise of medium and long slender grains.

Fig. 7. Grain type of NRRI varieties.

The varieties are bred considering the yield and tolerance to stresses. However, grain quality is an important trait for millers and consumers. Accordingly, NRRI varieties are analyzed for different quality parameters such as hulling, milling and head rice recovery (Fig. 8). The mean hulling, milling and head rice recovery for NRRI varieties are 78.6%, 66.75% and 56.06%, respectively. The varieties namely Sonamani, Lunabarial and Tapaswini showed HRR of > 66%, Dharitri, Radhi and Gayatri showed milling percentage of >70%. However, varieties namely Kalyani-II, Kalinga-II and Dhala Heera showed very less head rice recovery.

3.8. Kernel length, width and its ratio

The consumer preference of rice mostly depends on the grain quality, especially grain length and width. The analysis of NRRI varieties for kernel length showed ~21 varieties has grain length of > 6mm, whereas the mean grain length of NRRI varieties is 5.53mm. Similarly, the mean grain width of NRRI varieties is 2.08mm and 60 varieties showing grain width of more than 2mm (Fig. 9). The varieties namely HUE, Geetanjali, Poorna bhog, Satyakrishna showed higher grain length to width ratio of > 3.4.

3.9. Alkali spread value and water uptake /100g

The alkali spread value of NRRI varieties varied between three to seven. 30 varieties showed ASV of three, 41 varieties showed ASV of 4, four varieties showed ASV of 5, seven varieties showed ASV of 6 and four varieties namely Tara, Chandan, Poorna Bhog and Sudabahar showed ASV of 7 (Fig. 10). Similarly, the mean value of water uptake for NRRI varieties was found to be 122.15 ml/100 g of grain. The varieties namely, Tara, CRDhan 201, Shaktiman, CRDhan 205, Sneha, and Chandan showed higher water uptake of >200 ml/100g.

Fig. 8. Hulling, milling and head rice recovery of NRRI varieties

Fig. 9. Kernal length, kernel width and its ratio of NRRI varieties.

Fig. 10. Alkali spread value and water uptake of NRRI varieties

Fig. 11. Elongation ratio (ER), Volume expansion ratio (VER) and kernel length after cooking (KLAC) of NRRI varieties

3.10. Elongation ratio (ER), Volume expansion ratio (VER) and kernel length after cooking (KLAC)

The mean ER, VER, and KLAC of NRRI varieties are 1.69, 3.73, and 9.34, respectively (Fig.11). Elongation ratio of 17 varieties was found to be >1.8. Volume expansion ratio of 11 varieties were found to be ≥ 4 and KLAC is >10 in 21 varieties. The varieties namely, Geetanjali, HUE, Heera, CR Dhan 305, Reeta, Lunashanki showed higher KLAC values as compared to other varieties. Similarly, varieties namely Sneha, CRDhan 601, Indira, Abhishek showed higher ER as compared to other varieties. Phalguni, Sahbhagidhan, Abishek, CRDhan 601, Ketekijoha and CRDhan 201 showed higher volume expansion ratio as compared to other varieties.

4. Response of NRRI varieties to biotic stresses

4.1. Blast

Eighty NRRI varieties were evaluated for leaf blast in Uniform Blast Nursery (UBN) at NRRI, Cuttack. The disease reaction was scored visually on a 0-9 scale following the Standard Evaluation System (SES), IRRI (2013). Based on the screening scores against leaf blast, nineteen varieties (23.75%) were found highly resistant (Score 0-3), twenty-one varieties (26.25%) were moderately resistant (score 4-5), and forty varieties (50%) were found susceptible (score 6-9) (Fig. 12, Annexure III).

4.2. Brown spot

A set of 102 NRRI varieties were evaluated against brown spot disease of rice. Based on the screening scores, seventeen varieties (16.67%) were found moderately resistant; forty nine varieties (48.04%) were moderately susceptible, and thirty six varieties (35.29%) were found highly susceptible (Fig. 13, Annexure IV).

4.3. Sheath blight

Ninety eight NRRI varieties were artificially screened against sheath blight disease. The results showed that 9 varieties are moderately resistant, 7 varieties are tolerant, 9 varieties are moderately tolerant, 41 varieties are susceptible and 32 varieties are highly susceptible. However, none of the varieties was found to be resistant to sheath blight disease (Fig. 14, Annexure V).

Fig. 12. Response of NRRI varieties to leaf blast.

Fig. 13. Response of NRRI varieties to brown spot.

Fig. 14. Response of NRRI varieties for sheath blight.

4.4. Bakanae

One hundred and two NRRI released varieties were screened against bakanae disease of rice. Based on the screening results, the varieties were categorized into highly resistant (6); resistant (5); moderately resistant (25); moderately susceptible (10); susceptible (11) and highly susceptible (45). The disease incidence was recorded between 1.50 to 100%. Sadabahar recorded minimum level of disease incidence (1.50%) followed by Sarasa and CR Dhan 311 (3.5%) disease incidence (Fig. 15, Annexure VI).

Fig. 15. Response of NRRI varieties to bakanae disease.

4.5. Seedling blight

A total of 98 varieties were evaluated against seedling blight of rice caused by *Sclerotium oryzae* (Fig. 16, Annexure VII). Based on the screening score, 98 NRRI varieties were divided into highly resistant (6), resistant (17), moderately resistant (10), susceptible (27) and highly susceptible (38).

Fig. 16. Response of NRRI varieties for seedling blight.

4.6. Brown plant hopper (BPH)

Eighty nine NRRI varieties were screened against brown plant hopper in rice. Among them, 81 varieties were found to be highly susceptible; 5 varieties have shown susceptible reaction; one variety (Kalashree) was moderately susceptible and two varieties were found (Luna Sampad and Lunishree) to be moderately resistant. The minimum dead plant percentage was recorded in variety Lunishree (29.09%). Moreover, twenty nine varieties showed 100% dead plants (Fig. 17, Annexure VIII).

Fig. 17. Response of NRRI varieties to brown plant hopper.

4.7. Gall midge

A total of 91 NRRI released varieties were evaluated against rice gall midge in glass house condition. Among the varieties, 87 were highly susceptible, three varieties were found to be susceptible and only one variety (Samalei) was found to be highly resistant. There was no infestation in Samalei and twenty six varieties recorded 100% silver shoots (Fig. 18, Annexure IX).

Fig. 18. Response of NRRI varieties to gall midge.

4.8. Root knot Nematode

Sixty six NRRI varieties were evaluated against rice root knot nematode (*Meloidogyne graminicola*). Based on the gall index rating, two varieties were found to be moderately resistant (Scale-2), fourteen varieties were moderately susceptible (Scale-3), twenty eight varieties were susceptible (Scale-4) and twenty two varieties were found to be highly susceptible (Scale-5). The maximum gall per roots was found in variety Heera (148.33) and the minimum was recorded in CR Dhan 303 (4.5) (Fig. 19, Annexure X).

Fig. 19. Response of NRRI varieties to nematodes.

4.9. Multiple biotic stress tolerant NRRI varieties

The response of NRRI varieties to eight biotic stresses was compared to identify the multiple biotic stress resistant varieties. The analysis showed 51 varieties were found to be resistant to one biotic stress. Eight and two varieties were found to be resistant to two and three biotic stresses, respectively (Table 3, Fig. 20). Further, susceptible response was identified in the most of the NRRI varieties (Fig. 21). The identified multiple biotic stress tolerant rice varieties could be used for the crop improvement program.

Fig. 20. No. of multiple biotic stress resistant NRRI varieties

Fig. 21. Response of NRRI varieties to eight different biotic stresses

Table 3. NRRI varieties resistant to multiple biotic stresses.

Sl.No.	Varieties	Resistance for biotic stresses
1	Chandrama	Blast, Seedling blight
2	CR Dhan 311 (Mukul)	Seedling blight and Bakanae
3	Khira	Seedling blight and Bakanae
4	Lunishree	Blast, Seedling blight
5	Neela	False smut, Seedling blight, Bakanae
6	Sadabahar	Seedling blight and Bakanae
7	Samalei	Gall midge, Blast, Seedling blight
8	Sarasa	Blast, Seedling blight, Bakanae
9	Savitri	Blast, Seedling blight
10	Swarna Sub1	False smut, Bakanae, Seedling blight

5. Response of NRRI varieties to abiotic stress

5.1. Submergence

Submergence is one of the major abiotic stresses in eastern India. The selected (40 nos.) NRRI varieties were evaluated for the tolerance to the submergence stress. The analysis showed except the Swarna-Sub1, remaining varieties was found to be susceptible to submergence stress. In recent times, varietal improvement program in NRRI gives special emphasis to the submergence tolerance and varieties CR Dhan 801, CR Dhan 802 have been developed. Accordingly, several improved lines particularly in popular cultivars namely Pooja-Sub1, Maudamani-Sub1, Pratikshya-Sub1, and LalatMAS-Sub1 for submergence tolerance have been developed and in advanced stage of testing.

5.2. Stagnant flooding

Stagnant flooding also significantly reduces the yield of the varieties. The NRRI varieties were evaluated for stagnant flooding tolerance. Eight varieties were found to be tolerant to stagnant flooding. Interestingly, popular NRRI varieties such as Pooja, Sarala, and Gayatri were found to have stagnant flooding tolerance of up to 30cm water depth (Fig. 22). Further varieties namely Kalashree, Varshadhan, and Hansheswari showed stagnant flooding tolerance of up to 50-60cm of water depth. Thus, new breeding lines for shallow low lands can also be screened for stagnant flooding to increase the yield stability, especially for cultivation in Odisha.

Fig. 22. Stagnant flooding tolerance of NRRI varieties.

Fig. 23. Spikelet sterility of selected NRRI varieties for high temperature stress in field condition.

5.3. High temperature

The mean temperature is increasing due to climate change in different parts of the world. In Odisha, dry season rice crop is highly susceptible to high temperature stress during the reproductive stage. The NRRI varieties were evaluated for spikelet sterility under high temperature stress through staggered sowing (Fig. 23). Twenty one varieties showed average spikelet sterility of ~20%. Varieties namely Geetanjali, Tapaswinin, CR Dhan 303 showed sterility of more than 25%. Further, the variety Lunasanki was found to be moderately tolerant to high temperature stress in field condition.

5.4. Root traits

The varieties released for the aerobic condition are specifically adapted for better root growth. Thus, nine aerobic NRRI varieties were evaluated for the root length, total number of roots and number of roots at the base during seedling stage (Fig. 24). The analysis showed that mean root length at seedling stage was found to be ~29cm with maximum in CR Dhan 202. Similarly, maximum number of roots was recorded in CR Dhan 203 (60 roots per seedling). Additionally, CR Dhan 206 showed highest number of roots at the base per hill as compared to other aerobic varieties.

Fig. 24. Root characters of aerobic NRRI varieties.

6. Grain quality of NRRI varieties

6.1. Resistant starch and glycemic index analysis

The glycemic index of NRRI varieties were found to be in the range of 57.5 to 76.39. Varieties namely Shaktiman, Savitri, Supriya, and improved Lalat showed glycemic index of < 60 with mean glycemic index (64.59) (Fig. 25, Annexure XI). Similarly, ten varieties showed higher amount of resistant starch (≤ 2) as compared to other varieties. The mean value of resistant starch for NRRI varieties is 1.12. Varieties namely Gayatri, Kalashree, Jayanti Dhan, Swarna MAS are having higher resistant starch.

6.2. Aromatic rice varieties

NRRI has released so far ten aromatic rice varieties namely, Nuakalajeera, NuaDhusara, NuaChinikamini, Ketekijoha, Geetanjali, Poorna Bhog, CR Sugandh Dhan 907, CR Sugandh Dhan 908, CR Sugandh Dhan 909, and CR Sugandh Dhan 910. The aromatic varieties have been released for different ecologies such as irrigated late, shallow lowlands, and shallow favorable lowlands. Further, duration of the aromatic varieties ranged between 130-150 days according to the different ecologies. The yield of the aromatic varieties ranged from $3.0\text{--}5.0 \text{ t ha}^{-1}$ and recently released varieties (CR Sugandh Dhan 907, CR Sugandh Dhan 908, CR Sugandh Dhan 909, and CR Sugandh Dhan 910) showed relatively higher yield as compared to earlier released varieties.

Fig. 25. Resistant starch and glycemic index of NRRI varieties.

7. Straw quality of NRRI rice varieties

Nowadays, rice straw utilization is becoming one of the essential research areas due stubble burning in Northern India. There are several properties of paddy straw namely dry matter, nitrogen dry matter, ash, silica, fibre content, metabolizable energy determines the utility of the straw for different purposes such as mushroom cultivation, in-situ and ex-situ decomposition. NRRI varieties have been evaluated for nine different parameters related to straw quality (Table 4). The analysis showed that dry matter of the straw was found to be positively correlated with lignin content (Fig. 26). Similarly, in-vitro organic matter digestability was found to be positively correlated with total metabolizable energy of the straw. Nitrogen content in the dry matter of the straw was found to be positively correlated with silica content but negatively correlated with the neutral detergent fibre content in the NRRI varieties. Variety Abhishek and Ajay was found to have higher in-vitro organic matter digestability, nitrogen dry matter content, and least neutral detergent fibre content. Therefore, these varieties can be considered for in-situ and ex-situ decomposition.

7.1. Neutral and acid detergent fibre content of NRRI varieties

Fibre content of the straw determines the organic decomposition rate of paddy straw. Average neutral fibre (NDFDM), acid detergent (ADFDM) and lignin content (ADLDM) was found to be 66.18%, 51.67% and 4.53%, respectively (Fig. 27). Varieties namely Panidhan,

Satyakrishna, Savitri and Reeta has higher neutral detergent fibre content, Lunasanki, Maudamani has higher acid detergent fibre content and Pyari and Khitish has higher lignin content. The fibre content of paddy straw will be highly useful for identification of genotypes suitable for different methods of decomposition.

Table 4. Correlation of different straw related traits of NRRI varieties.

	DM	Ash	NDM	NDFDM	ADFDM	ADLDM	Silica	ME	IVOMD
DM	1								
Ash	0.0019385	1							
NDM	0.1055189	0.5801693	1						
NDFDM	0.0887412	-0.8030155	-0.6797367	1					
ADFDM	-0.1954939	0.351951	-0.123685	-0.0217486	1				
ADLDM	0.7623904	0.0835959	0.292741	-0.0661183	0.0589385	1			
Silica	-0.2212919	0.811149	0.508814	-0.8064402	0.5661085	0.102609	1

IVOMD	-0.1350044	-0.2419463	-0.2206995	0.2562043	-0.5847606	-0.4659074	-0.5837476	0.484338	1

DM-Dry matter, NDM-Nitrogen content in dry matter basis, NDFDM-Neutral detergent fibre on dry matter basis, ADFDM-Acid detergent fibre on dry matter basis, ADLDM-Acid detergent lignin on dry matter basis, ME-Metabolizable energy, IVOMD-In-vitro organic matter digestability

Fig. 26. Different dry matter fraction of rice straws of NRRI varieties.

(NDFDM-Neutral detergent fibre on dry matter basis, ADFDM-Acid detergent fibre on dry matter basis, ADLDM-Acid detergent lignin on dry matter basis).

Fig. 27. Relationship between metabolizable energy (ME) and in-vitro organic matter digestability (IVOMD) of rice straw in NRRI varieties.

7.2. In-vitro organic matter digestibility and metabolizable energy

In-vitro organic matter digestability is the best indicator for paddy straw decomposition. The relationship between the metabolizable energy and in-vitro organic matter digestability was found to be positively correlated (Fig. 28) and showed increasing trend in linear regression ($Y= 2.11x+26.67$), where Y is the organic matter digestability and x is the metabolizable energy in the straw. The varieties namely Neela, Reeta, Varshadhan, Lunishree, and Shatabdi showed higher in-vitro organic matter digestability as compared to other NRRI varieties.

Fig. 28. Relationship between neutral detergent fibre content (NDFDM) and nitrogen in dry matter (NDM) of rice straw in NRRI varieties.

7.3. Nitrogen in dry matter and neutral detergent fibre content of paddy straw

The nitrogen dry matter (NDM) and neutral detergent fibre content (NDFDM) was negatively correlated and regression trend was also found to be negative with R² value of 0.462. Varieties namely Kalinga-II, Ajay, Neela, Anjali and Radhi showed higher nitrogen content but lower neutral detergent fibre content. Similarly, varieties namely Varshadhan, Utkalprava, Udaya and Supriya showed higher fibre content as compared to other varieties. Thus, the analysis provides vital information for selection of paddy straw of NRRI released varieties for different purposes.

8. Research priorities

ICAR-NRRI has released around 139 rice varieties during the last 50 years. The present analysis showed different varietal traits including grain quality and biotic/abiotic stress response. This analysis provides several research insights which could be considered for the development of the new varieties in future. The research insights and future priorities are given below.

Sl. No	NRRI Achievements	Research insights	Suggestions
1	NRRI has released 139 rice varieties. MAS varieties for submergence, drought, and bacterial leaf blight have been successfully developed	~10% of NRRI varieties released after 2009 were developed through marker assisted backcross breeding	Efforts needs to be taken to increase MAS varieties up to 25%. Trait improvement through introgression of brown plant hopper resistance genes into high yielding varieties could be considered
2	In total, 54 NRRI varieties are in formal seed chain	~20% of NRRI varieties in seed chain are having 5 qt/year breeder seed indent	Efforts should be made to promote at least 20% of newly released NRRI varieties in seed chain
3	NRRI varieties are released for 10 different ecologies. Varieties such as Swarna-Sub1 and Shabtagidhan are very popular for flood prone shallow lowlands, and rainfed upland ecologies	Only 20% of varieties are released for shallow lowlands	Since large area in eastern India comes under shallow low lands, more emphasis needs to be given for varietal development in shallow lowlands
4	Yield trend analysis showed that higher yield increase over years was observed for deep and medium-deep, followed by irrigated, shallow lowland and upland ecologies	Costal-salinity, aerobic ecosystem showed stagnant yield over years	Yield QTLs/genes can be introgressed specifically for shallow lowlands, coastal-salinity, aerobic ecologies for yield improvement of NRRI varieties
5	Increase in duration of NRRI varieties increased yield for ecologies namely semi-deep, deep-water, aerobic, irrigated and upland varieties	Shallow lowland, coastal salinity and medium-deep ecologies showed opposite trend for increase in the duration	
6	37% of NRRI varieties are resistant to at least one biotic stress	~12% of NRRI varieties showed resistance to more than one biotic stresses	The identified varieties can be utilized as donors in crop improvement program

9. Future challenges

The varieties of NRRI have contributed significantly to the national food security. However, there is a need to revise the priorities of rice improvement program due to climate change, fluctuating market price, reduced income gain for the farmers. The immediate requirement is to replace the popular rice cultivars with new cultivars having multiple tolerances to biotic and abiotic stresses. Additionally, rate of increase in the yield of the NRRI varieties is very small and follows the similar trend of national average. Thus, greater emphasis needs to be given in increasing the farm yield of the rice varieties by combination of conventional and molecular approaches. Moreover, increasing the profitability of rice cultivation requires multi-pronged strategy for enhancing the input use efficiency, and grain quality.

10. Conclusion

ICAR-NRRI has released 139 rice varieties including three hybrids. Response of varieties to biotic/abiotic stresses and grain quality provide first hand information in structuring the rice improvement program. Additionally, analysis of different traits of NRRI varieties provides an important link in understanding the popularity of NRRI varieties among the farmers. Further, integration of all these varietal information will provide vital clues about the major bottlenecks in-terms of yield, quality and response to biotic/abiotic stresses. Thus, the present research bulletin on the various traits of NRRI varieties could be highly useful in structuring the breeding program for the future need of the nation, especially for the rice farmers in eastern India.
